Don’t forget to floss and floss so you don’t forget? Emerging evidence linking periodontal disease and dementias

A peer-reviewed article written by Mia L. Geisinger, DDS, MS
Don’t forget to floss and floss so you don’t forget? Emerging evidence linking periodontal disease and dementias

Abstract
Patients with periodontal disease are significantly more likely to develop Alzheimer’s disease than those who are periodontally healthy. This interaction is thought to be mediated by inflammation, the periodontal microbiome, and the immune reactions to those pathogens that are associated with the oral biofilm. The elderly population in the United States is expected to nearly double by the year 2050. Currently, over 5 million adults in the United States suffer with dementia. The generation that makes up the growing elderly population has rates of total edentulism that are dropping precipitously. Furthermore, medications for dementia often increase symptoms of xerostomia, and higher caries rates are seen in patients with dementia, particularly those with moderate to severe disease and/or those who reside in residential nursing care facilities. It follows, therefore, that many older adults are dentate and suffering with dementia and will require dental care that is delivered or facilitated by primary care providers. There is a need for protocols that allow for effective oral home care for dementia patients, while minimizing care-resistant behaviors, as well as nonsurgical interventions for patients with caries and/or periodontal disease. This course seeks to improve the dental care provider’s understanding of the interaction between periodontal disease, dental caries, and dementia. It will also serve as an aid in the clinical decision-making process to optimize dental health for patients with dementia and periodontal disease.

Educational objectives
Upon completion of this course, the dental professional should be able to:
1. Understand the current scientific literature about the prevalence, etiology, and stages of dementia
2. Recognize and discuss with patients the association of periodontal diseases and oral bacteria with dementia and Alzheimer’s disease
3. Develop and implement strategies for communication and delivery of oral hygiene and dental care to patients suffering with dementia
4. Evaluate patients’ risk factors and oral hygiene to develop effective intervention and treatment modalities to reduce caries and periodontal disease rates

This continuing education (CE) activity was developed by Endeavor Business Media with no commercial support. This course was written for dentists, dental hygienists, and dental assistants, from novice to skilled.

Educational methods: This course is a self-instructional journal and web activity.

Provider disclosure: Endeavor Business Media neither has a leadership position nor a commercial interest in any products or services discussed or shared in this educational activity. No manufacturer or third party had any input in the development of the course content.

Presenter disclosure: Author discloses that they do have a leadership or financial relationship to disclose related to this continuing education activity.

Requirements for successful completion: To obtain three (3) CE credits for this educational activity, you must pay the required fee, review the material, complete the course evaluation, and obtain an exam score of 70% or higher.

CE planner disclosure: Laura Winfield, Endeavor Business Media dental group CE coordinator, neither has a leadership nor commercial interest with the products or services discussed in this educational activity. Ms. Winfield can be reached at winfield@endeavorinc.com or 800-633-1681.

Educational disclaimer: Completing a single continuing education course does not provide enough information to result in the participant being an expert in the field related to the course topic. It is a combination of many educational courses and clinical experience that allows the participant to develop skills and expertise.

Image authenticity statement: The images in this educational activity have not been altered.

Scientific integrity statement: Information shared in this CE course is developed from clinical research and represents the most current information available from evidence-based dentistry.

Known benefits and limitations of the data: The information presented in this educational activity is derived from the data and information contained in the reference section.

Registration: Rates for print CE have increased due to the manual nature of producing and grading courses in this format. For a lower-cost option, scan the QR code or go to dentalacademyofce.com to take this course online. MAIL/PAX: $69 for three (3) CE credits.

Digital: $39 for three (3) CE credits.

Cancellation and refund policy: Any participant who is not 100% satisfied with this course can request a full refund by contacting Endeavor Business Media in writing.

Provider information:
Endeavor Business Media is a nationally approved PACE program provider for FAGD/MAGD credit. Approval does not imply acceptance by any regulatory authority or AGD endorsement.

ACE Exam: 11/1/2019 to 10/31/2024. Provider ID# 320452

ADA code: 490

“THIS course meets the Dental Board of California’s requirements for three (3) units of continuing education.”

American Association of Dental Schools
Endeavor Business Media is designated as an approved provider by the American Academy of Dental Hygiene, Inc. MADAH/PHD (January 1, 2021 – December 31, 2024). Approval does not imply acceptance by any regulatory authority or AGD endorsement.

ADA CERP
ADA CERP is a service of the American Dental Association to assist dental professionals in identifying qualified providers of dental continuing education. ADA CERP does not approve or endorse individual courses or instructors, nor does it imply acceptance of credit hours by boards of dentistry. Concerns or complaints about a CE provider may be directed to the provider or to ADA CERP at ada.org.

Endeavor Business Media is an ADA-CERP recognized provider.

Provider ID# 320452

QUICK ACCESS code 22123
Dementia is the most frequent neurological disease and is recognized as a global public health priority by the World Health Organization. Due to the aging of the population, treatment costs for dementia are expected to more than triple by 2050. While treatments to reduce and/or delay dementia symptoms have been studied, there has not been an effective method to prevent or manage dementia for the long term. Dementia causes loss of cognitive function and interferes with a patient’s ability to perform activities of daily living and to participate in social activity. Although dementia is not solely a disease of the elderly, the most common form is degenerative brain disease, such as Alzheimer’s disease (AD) or vascular dementia. As the global elderly population increases, the prevalence of dementias will also likely increase. Systemic and environmental factors have been associated with increased incidence of dementia including: low educational attainment, nicotine use, physical inactivity, depression, hypertension in middle age, diabetes mellitus, and overweight/obesity status. Further, systemic inflammation has been associated with dementia development. Given these findings, with protocols to treat associated diseases in at-risk patients, it may be possible to prevent and/or delay dementia development and extend the healthy life span.

Oral health status has been strongly associated with dementia. This relationship may be bidirectional and multifactorial; impaired cognitive function can impact oral hygiene delivery and inflammation related to periodontal disease, and subsequent tooth loss may impact dementia development. Inflammatory mediators closely associated with periodontal disease, e.g., C-reactive protein (CRP), interleukin 6 (IL-6), interleukin 1β (IL-1β), and tumor necrosis factor α (TNF-α), have been identified as playing a potential role in the development and/or progression of dementias. An "inflammatory model" linking periodontal disease and dementias posits that systemic inflammatory markers that are elevated in patients with periodontal disease progression can stimulate the production of beta amyloid and tau protein in brain tissue and increase the permeability of the blood-brain barrier, which may increase the risk of development and/or increase the rapidity of symptom onset in individuals with dementia.

This course will discuss the interaction between periodontal disease and dementia, the impact of dementias on overall oral health, and the effect of periodontal therapy on dementia disease activity. In fact, a recent study gained much lay media attention after the authors found that brain tissue from elderly individuals contained higher levels of gingipain enzymes from Porphyromonas gingivalis (P. gingivalis) than in healthy controls. As oral biofilm accumulates, it shifts from a eubiotic biofilm associated with health to a more dysbiotic and periodontopathogenic biofilm. Such dysbiotic biofilms are associated with both gingivitis and periodontitis. As the biofilm becomes more pathogenic, the number and proportion of strict anaerobic species present within the biofilm mass increase. Anaerobic and motile organisms associated with periodontitis have been associated with systemic bacteremias, particularly in the presence of gingival inflammation. These bacteremias occur during day-to-day procedures such as mastication and toothbrushing. It is feasible, therefore, that in cases of gingival inflammation, either due to gingivitis or periodontitis, the associated systemic translocation of pathogenic bacterial species may result in bacterial entry into brain tissues and potentially negatively impact neural tissues and cognition.

Epidemiology and etiology of common dementias

Dementia cannot be considered a natural consequence of aging or even extreme forgetfulness. Dementia is defined by its progressive and chronic nature. Patients with dementia experience deterioration in memory, thinking, behavior, and the ability to perform everyday activities. Currently, more than 55 million people live with dementia worldwide, and there are nearly 10 million new cases every year. Furthermore, global estimates suggest that the total economic costs caused by dementia increased from US $279.6 billion in 2000 to $948 billion in 2016, with an annual growth rate of nearly 16%. It is estimated that attributable dementia spending will reach $1.6 trillion by 2050. Given the considerable economic and societal burdens associated with dementia, understanding the underlying risk factors and implementing public health measures to reduce the overall burden in the future is critically important.

Prevalence and distribution of patients with dementia

Dementia is growing at alarming rates in all regions of the world and is proportional to population aging. It is projected that the number of people with dementia will increase from an estimated 57.4 (50.4 to 65.1) million cases globally in 2019 to an estimated 152.8 (130.8 to 175.6) million cases in 2050. Globally, 1.62 million (0.41-4.21) people were estimated to have died of end-stage dementia in 2019, and mortality due to dementia is expected to rise in coming years. The prevalence of dementia increases dramatically with age; 3% of people age 65-74, 17% of people age 75-84, and 32% of people age 85 or older have Alzheimer’s dementia.

Different types of dementias

Alzheimer’s disease is the most common form of dementia, causing approximately two-thirds of all cases of dementia. Other major forms of dementia are vascular dementia (affecting up to 20% of patients with dementia), dementia with Lewy bodies (approximately 15% of all dementia cases), frontotemporal dementia (less than 5% of dementia cases), and HIV/AIDS, traumatic brain injury, and Wernicke-Korsakoff syndrome (includes dementia from alcohol abuse). The boundaries between different forms of dementia are indistinct, and mixed forms, as well as dementia as a comorbidity with other diseases, may coexist. Additionally, less common forms of dementia include: Parkinson’s disease dementia, Huntington’s disease, Creutzfeldt-Jakob disease and other prion diseases, dementia in HIV/AIDS, traumatic brain injury, and Wernicke-Korsakoff syndrome (includes dementia from alcohol abuse). Risk factors for dementia are multifactorial and vary throughout life. Educational attainment early in life, e.g., number of years spent in education, and
protective against dementia, and a higher level of educational attainment as well as continued education/learning throughout life may delay dementia onset. Additionally, hypertension, diabetes mellitus, hyperlipidemias, alcohol use, diet, and smoking are associated with increased risk of dementia development, whereas increased cognitive activity, social activity, and exercise may negatively influence dementia development. Late-onset Alzheimer’s, the most common form of dementia, is thought to have multifactorial etiology. This form of dementia is generally thought to be due to a “multi-hit” hypothesis, where development of the disease is due to a combination of genetic, lifestyle, and environmental factors. Genetically, a polymorphism of the apolipoprotein E (APOE) gene, specifically APOE e4 on chromosome 19, increases an individual’s risk for developing late-onset Alzheimer’s disease. This gene and others are thought to increase the risk of Alzheimer’s disease development by increasing the production of prese-nilin and β-amyloid precursor protein (BAPP). The presence of these proteins have been shown to enhance deposition of β-amyloid protein in brain tissue. In addition to these genetic risk factors, epigenetic alterations of the genome (modification of the genome to turn genes off) may play a role for environmental and lifestyle factors to influence gene expression and ameliorate or potentiate underlying genetic risk factors. Studies have also identified blood-brain barrier dysfunction, including: 1) increased permeability, 2) microbleeds, 3) impaired nutrient transport, and 4) impaired learning of neurotoxins, as a mechanism for introduction of neurotoxic substances, e.g., bacteria and bacterial by-products, into the brain.

Cognitive impairment classifications
It can be difficult to pinpoint the exact onset of dementia as symptoms progress along a spectrum with increasing severity over time and progression speed is dependent on myriad patient-related and environmental factors. Progression generally occurs from no impairment to very severe dementia, with early symptoms being subclinical in many patients. Both the Global Deterioration Scale/Reisberg Scale and the Functional Assessment Staging Test (FAST) assign seven stages to the progression of dementia (Table 1).

Epidemiology and etiology of periodontal disease
Periodontal diseases include inflammatory diseases of the supporting structures around the teeth—the gingiva, periodontal ligament, alveolar bone, and cementum. Research shows all individuals are susceptible to gingivitis, a reversible form of gingival inflammation. Additionally, gingivitis may be the precursor to more serious, irreversible forms of periodontal diseases. Gingivitis is caused by dysbiotic oral biofilm and, in general, gingivitis severity is related to the amount and type of bacteria that have accumulated at and

<tr>
<th>Stage</th>
<th>Symptoms</th>
<th>Diagnosis</th>
</tr>
</thead>
<tbody>
<tr>
<td>No dementia</td>
<td>Stage 1: No cognitive decline</td>
<td>In this stage, a person functions normally and has no memory loss and is mentally healthy. People without dementia would be in stage 1.</td>
</tr>
<tr>
<td>No dementia</td>
<td>Stage 2: Very mild cognitive decline</td>
<td>This stage is used to describe normal forgetfulness associated with aging, for example, forgetting names and where familiar objects were left. Symptoms of dementia are not evident to the individual or their physician.</td>
</tr>
<tr>
<td>No dementia</td>
<td>Stage 3: Mild cognitive decline</td>
<td>This stage includes increased forgetfulness, slight difficulty concentrating, and decreased work performance. People may get lost more frequently or have difficulty finding the right words. At this stage, a person’s loved ones will begin to notice a cognitive decline.</td>
</tr>
<tr>
<td>Early stage</td>
<td>Stage 4: Moderate cognitive decline</td>
<td>This stage includes difficulty concentrating, decreased memory of recent events, and difficulties managing finances or traveling alone to new locations. People may have trouble completing complex tasks efficiently or accurately and may be in denial about their symptoms. They may also start withdrawing from family or friends because socialization becomes difficult. At this stage, a physician can detect clear cognitive problems during a patient interview and exam.</td>
</tr>
<tr>
<td>Midstage</td>
<td>Stage 5: Moderately severe cognitive decline</td>
<td>People in this stage have major memory deficiencies and need some assistance to complete their daily living activities (dressing, bathing, preparing meals, etc.). Memory loss is more prominent and may include major relevant aspects of current lives. For example, people may not remember their address or phone number and may not know the time of day or where they are.</td>
</tr>
<tr>
<td>Midstage</td>
<td>Stage 6: Severe cognitive decline (middle dementia)</td>
<td>People in stage 6 require extensive assistance to carry out their activities of daily living (ADL). They start to forget names of close family members and have little memory of recent events. Many people can remember only some details of earlier life. Individuals also have difficulty counting down from 10 and finishing tasks. Incontinence (loss of bladder or bowel control) is a problem. Ability to speak declines. Personality/emotional changes, such as delusions (believing something to be true that is not), compulsions (repeating a simple behavior, such as cleaning), or anxiety and agitation may occur.</td>
</tr>
<tr>
<td>Late stage</td>
<td>Stage 7: Very severe cognitive decline (severe dementia)</td>
<td>People in this stage have essentially no ability to speak or communicate. They require assistance with most activities (e.g., using the toilet, eating). They often lose psychomotor skills, for example, the ability to walk.</td>

</tbody>
</table>
the prevalence of periodontitis among US adults is nearly fourfold greater than that of diabetes mellitus and over sixfold greater than that of coronary artery disease. Periodontitis is extremely prevalent, and after initiation by bacteria and bacterial virulence factors, disease progression and tissue destruction occurs through host-mediated inflammatory pathways, which may vary based upon genetic and other risk factors. The result is a chronic immunoinflammatory disease that may pose a significant systemic burden for individuals.

**Associations between dementias and periodontal disease**
Periodontal disease results in systemic inflammation and the potential for bacterialemia, both of which may impact other organ systems. Periodontitis has been linked to cognitive impairment and dementia after controlling for confounding factors such as age, sex, and educational attainment. Disease progression in periodontal disease is associated with dysbiosis and elevated chronic inflammation, and dementia and Alzheimer’s disease have been linked to periodontal disease through both inflammatory and bacterial mechanisms.

Periodontitis stage is assigned as I–IV and is determined by patients’ current disease presentation, including attachment, bone, and tooth loss, and the case complexity. Periodontitis grade is defined as A–C and is based upon risk and evidence of the rapidity of disease progression over time.

The prevalence of periodontitis has been estimated to be over 42% of US adults over 30 years of age. Of those individuals, 7.8% had severe periodontitis, and severe periodontitis was most prevalent among adults 65 years of age or older, Mexican Americans, non-Hispanic blacks, and smokers. These statistics suggest that
to the bacteria themselves, influence on the brain by bacterial by-products including virulence factors such as lipopolysaccharide, capsular material, proteolytic enzymes, and gingipains may contribute to the progression of dementia.\textsuperscript{13,69,70,73} It should be noted that the presence of gingipains, in particular, has been associated with increases in tau protein and potential worsening of dementia.\textsuperscript{13} Finally, epigenetic alterations of the host genome as a result of exposure to bacteria and/or their by-products may alter gene expression and influence the risk conferred by those genes. Bacteria and their by-products have been shown to increase DNA methylation and histone acetylation, which has been indicated in the development of periodontal disease, cancers, and other diseases.\textsuperscript{74,75}

Oral hygiene status and oral microbiome composition in elderly dentate patients has also been associated with development of dementia.\textsuperscript{76} Alteration of the oral microbiome may be achieved through oral hygiene interventions, which then can alter serum levels of microorganisms and change a potential pathway for bacteria and their by-products to cross the blood-brain barrier.\textsuperscript{68,70,77} Oral dysbiosis is indicated as the primary etiology for both periodontitis and gingivitis, and those dysbiotic microbiota have been independently associated with invasion of soft tissues and bacteremias.\textsuperscript{14,15} Such systemic translocation of bacteria has been associated with myriad systemic diseases, including dementias.\textsuperscript{13,16,17,69-71} Given the impact of oral dysbiosis on systemic health, optimal oral home-care regimens, including care of teeth and dental implants as well as appropriate cleaning of removable prostheses, should be of a part of care delivery for individuals with dementia.\textsuperscript{78} Improved oral hygiene delivery is associated with decreases in dental diseases in these populations\textsuperscript{69,80} and has been suggested as an intervention to reduce the direct and indirect influences of oral bacteria and their by-products on the brain and the potential influence of these bacteria and their by-products on cognitive decline (figure 1).\textsuperscript{81}

The effect of periodontal therapy on dementia disease activity

Interventional studies assessing the impact of periodontal therapy on dementia are limited. It is well-established that meticulous oral hygiene and the use of some chemotherapeutic agents can address oral dysbiosis.\textsuperscript{82-84} While direct evidence of periodontal therapeutic intervention on dementia is limited, a recent study demonstrated that periodontal treatment had a favorable effect on Alzheimer’s disease-related brain atrophy.\textsuperscript{85} This may indicate that periodontal treatment could prevent or slow disease progression of dementias. Further, there is an ongoing phase II/III trial with the US Food and Drug Administration (FDA) to evaluate the use of a small-molecule inhibitor for gingipains and gingipain-binding sites (atuzaginstat [COR388, Cortexyme Inc.]). Animal studies have demonstrated that application of these inhibitors directly into the brains of mice orally infected with \textit{P. gingivalis} reduced the neural toxicity of gingipains.
Evidence has shown that the risk of developing dementia in a longitudinal analysis was significantly higher in those with untreated periodontal disease when compared to those receiving regular maintenance therapy. Periodontal therapies including mechanical debridement, local antimicrobial use, and extraction of hopeless teeth in patients with Alzheimer’s disease have also been shown to result in improvements in cognitive function. While it is unclear on the exact benefits of periodontal therapy in patients with cognitive impairment, the current evidence suggests that in addition to the oral health benefits, careful attention should be paid to this special population given the potential for cognitive benefits as well, due to microbial and inflammatory connections between periodontitis and dementias.

There are, however, significant challenges in treating patients with cognitive impairment, including communication, memory, at-home plaque control, and compliance with dental care visits. Some of the dilemmas that dental health-care providers can encounter in this patient population include:

- Diagnosis of dental conditions and/or patient complaints if/when the patient cannot relate signs and symptoms of disease to the dental health-care provider
- Assessment of pain/discomfort when sensory changes may influence pain perception
- Determination of diagnostic and therapeutic prognoses to assess likely disease progression without intervention
- Understanding the likely path of dementia disease progression and how that may impact oral care and oral disease progression

Dental health-care providers must also assess the ability of a patient with dementia and/or their caregiver to provide regular oral hygiene outside of the dental office and the behavioral and treatment modifications that may be necessary to deliver care for patients with dental needs. It is critical that dental health-care professionals speak with patients and caregivers about the associations between oral dysbiosis, periodontitis, and dementia and the potential positive impacts of regular preventive and/or interventional dental care in patients with or at-risk for developing dementia.

Patients with dementia can also exhibit care-resistant behaviors, which are defined as behaviors in which persons with dementia resist the help of health-care providers or caregivers. Dental health-care providers can employ techniques, including forming a connection by approaching the patient at or below eye level, using a friendly and calm attitude, and using brief, one-step commands. Caregivers should avoid elderspeak (sing-song tone of voice that is often used for babies/children and the elderly). Elderspeak use has been associated with an increase in care-resistant behaviors in adults with dementia.

Additionally, delivery of oral care in a familiar environment and providing a toothbrush or other oral care materials to a patient with dementia can reduce care-resistant behavior.

It is also imperative to assess nonverbal cues of dental pain/discomfort in patients with severe dementia. Some signs that a patient may be experiencing dental/oral pain include: chewing of lip or tongue, pulling at face or lips, refusing denture wear, and/or aggression in response to oral-related activities of daily living.
Figure 1 demonstrates some strategies that may be utilized to reduce care-resistant behavior both during professional dental care and when oral home care is being delivered by a caregiver (Figure 2).

Concerns regarding patients with dementia receiving ongoing dental care can include:

- Ability of the patient and/or caregiver to deliver regular oral hygiene
- Ability of the patient to tolerate dental interventions and the potential need for sedation
- Ability of the patient to give informed consent and/or assent to treatment
- Oral side effects of medications used to treat dementia symptoms and their implications for caries and periodontal disease development and progression

Given these concerns and implications, regular assessment of a patient’s cognitive impairment in the dental office and modification of treatment related to the level of cognitive ability are critical to the overall success of dental management for patients with dementia. Niessen et al. developed an index to assess the need for alterations in care delivery in an outpatient setting such as an independent dental office or a dental practice (Table 2). The most important factor that dental health-care professionals must evaluate is the patient and/or caregiver capacity for delivery of home care. This index assesses the following:

- Patient’s ability to perform activities of daily living. This can inform the determination of the level of occlusal functioning and types of prostheses that may be most beneficial to the patient (e.g., if the patient eats solid food and can feed themselves) and whether dental care delivery in an outpatient setting is feasible.
- Patient’s level of social functioning. This allows assessment of the behavioral expectations for a patient undergoing dental treatment and/or the potential need for conscious sedation and/or general anesthesia to allow for care delivery.
- Condition of the remaining dentition, including plaque index and caries and periodontal conditions. This may determine if teeth with hopeless or poor prognosis are present and should be extracted and the likelihood of worsening oral disease over time as cognitive impairment progresses.

Once the level of cognitive functioning is assessed, the dental health-care provider should determine appropriate treatment and intervention. Dental health-care professionals can educate patients and caregivers about the associations between unmanaged periodontal disease and dementia, as well as the beneficial potential of periodontal therapy in patients at risk for or diagnosed with dementia disease. Further aggressive preventive oral therapy should be employed if possible to potentially reduce future dental needs. The assessment and considerations are summarized in Table 3.

Table 3 summarizes the assessment and considerations.
Summary
Research has demonstrated epidemiologic and biologic associations between periodontal disease and a number of dementias. The current theory of the interaction between these conditions focuses on the translocation of the periodontal microflora and periodontitis-associated inflammatory mediators to the central nervous system, where the microflora and their by-products can induce inflammatory and destructive changes in neural tissues. The current and future development of inhibitors to key microflora, such as P. gingivalis, through enzyme (e.g., gingipain) inhibition may provide benefits in patients with dementia for oral and other diseases. Improved oral health has been associated with systemic health and well-being improvements including: improved nutritional intake and sleep patterns, decreased agitation associated with discomfort/pain, and improved appearance. Dental health-care providers have a duty to appropriately assess current health conditions and to evaluate the risks and benefits for safely delivering dental care in a manner that enhances patients’ oral and overall health.

Notes
1. A 2019 study examining brain tissue from elderly individuals found that gingipains from \( P. \) gingivalis were present at _____ levels in brains from individuals with Alzheimer’s disease than those who did not have Alzheimer’s disease.
   A. Higher
   B. Lower
   C. Similar
   D. Unknown

2. Approximately how many people are diagnosed with dementia every year worldwide?
   A. 2 million
   B. 5 million
   C. 7 million
   D. 10 million

3. The number of people with dementia will increase from an estimated 57.4 million cases globally in 2019 to an estimated ____ million cases in 2050.
   A. 75
   B. 110
   C. 153
   D. 202

4. Which of the following has not been associated with the development of dementia?
   A. Smoking
   B. High level of educational attainment
   C. Diabetes mellitus
   D. Hypertension

5. Which of the following genetic polymorphisms has been linked to an increased risk of late-onset Alzheimer’s disease?
   A. APOE e4
   B. IL-1β
   C. Angiotensin converting enzyme (ACE)
   D. Estrogen receptor-2

6. Chronic inflammation influences the progression of dementia. It has been hypothesized that inflammation primes the microglia and increases the production of neuronal proteins associated with dementia.
   A. Both statements are true.
   B. The first statement is true; the second statement is false.
   C. The first statement is false; the second statement is true.
   D. Both statements are false.

7. Studies show that blood-brain barrier dysfunction plays a role in the initiation and disease progression of dementia through the following mechanisms:
   A. Increased permeability
   B. Microbleeds
   C. Impaired learning of neurotoxins
   D. All of the above

8. Alzheimer’s disease is the most common form of dementia, causing approximately _____ of all cases of dementia.
   A. One-half
   B. Two-thirds
   C. Three-quarters
   D. Seven-eighths

9. Which of the following is not a major form of dementia?
   A. Vascular dementia
   B. Wernicke-Jakob
   C. Dementia with Lewy bodies
   D. Frontotemporal dementia

10. Which of the following is false?
    A. All individuals are susceptible to gingivitis.
    B. Gingivitis is reversible.
    C. Gingivitis severity is generally not related to the amount and type of oral biofilm present at the gingival margins of teeth.
    D. Gingivitis is modified by local factors (dental biofilm retentive factors and oral dryness) and systemic factors (smoking, metabolic factors, nutritional factors, pharmacologic agents, sex steroid hormone elevation, and hematologic conditions).

11. Average progression of periodontal disease demonstrates a slow to moderate rate of disease progression with approximately _____ mm of attachment loss and _____ teeth lost annually.
    A. 0.1; 0.2
    B. 0.2; 0.5
    C. 0.5; 0.5
    D. 0.8; 0.2

12. Periodontitis stage is assigned as A-D and is assessed by patients’ current disease presentation, including attachment, bone, and tooth loss, and the case complexity. Periodontitis grade is defined as I-III and is based upon risk and evidence of the rapidity of disease progression over time.
    A. Both statements are true.
    B. The first statement is true; the second statement is false.
    C. The first statement is false; the second statement is true.
    D. Both statements are false.

13. Among US adults over the age of 30, ____% have some form of destructive periodontitis.
    A. 16
    B. 27
    C. 42
    D. 61

14. Pathways by which oral bacteria are thought to enter the brain include:
    A. Bacteremia allows for bacteria within the bloodstream, and chronic infection, age, and inflammation increase the permeability of the blood-brain barrier.
    B. Bacteria may gain direct access to the brain through perivascular spaces.
    C. Bacteria may pass into the brain through olfactory and/or trigeminal nerve pathways.
    D. All of the above

    A. An increase
    B. No change
    C. A decrease
    D. Unknown effects

16. A small-molecule inhibitor for gingipains and gingipain-binding sites (atuzaginstat [COR389, Cortexyme Inc.]) has been tested in animals. Application of these inhibitors directly into the brains of mice orally infected with \( P. \) gingivalis resulted in:
    i. Reduced formation of amyloid plaques and tau tangles
    ii. Decreased gingipain toxicity
    iii. Reduction in \( Porphrymonas \) spp. intraorally
    iv. Reduction in periodontal disease destruction
    A. i and iv
    B. i only
    C. ii, iii, and iv
    D. All of the above
17. Periodontal therapies, including mechanical debridement, local antimicrobial use, and extraction of hopeless teeth, in patients with Alzheimer's disease have also been shown to result in ____ in cognitive function.
   A. An improvement
   B. No change
   C. Worsening
   D. Unknown effects

18. Which of the following is not a challenge in the treatment of patients with dementia?
   A. Diagnosis of dental conditions and/or patient complaints and when the patient cannot relate signs and symptoms of disease to the dental health-care provider
   B. Delivering sedation and/or general anesthesia in patients for behavioral management
   C. Assessment of pain/discomfort when sensory changes may influence pain perception
   D. Determination of diagnostic and therapeutic prognoses to assess likely disease progression without intervention

19. Care-resistant behavior is defined as:
   A. Persons with dementia withstand or oppose the helping efforts of caregivers
   B. Caregivers that induce agitation in persons with dementia
   C. Patients with dementia related to cognitive impairment, more aggressive interventions based upon a risk-benefit analysis. In patients with more severe cognitive impairment, more aggressive interventions are indicated.
   D. Caregivers who decrease the effectiveness of health-care delivery

20. Which of the following is a technique caregivers can implement to reduce care-resistant behavior?
   A. Approaching the patient above eye level
   B. Using elderspeak
   C. Using polite, one-step commands
   D. All of the above

21. Which of the following are signs of oral discomfort that may be recognized in a nonverbal patient with dementia?
   i. Chewing of lip or tongue
   ii. Pulling at face or lips
   iii. Refusing denture wear
   iv. Aggression in response to oral-related activities of daily living
   A. i, iii
   B. i, ii, iii
   C. i, ii, iii, iv
   D. iv only

22. Which is the most important factor that dental health-care professionals must evaluate when determining a dental treatment plan?
   A. Number of remaining teeth
   B. Insurance coverage for dental care
   C. Patient and/or caregiver capacity for delivery of home care
   D. Likelihood of improved cognition with periodontal care

23. Dental health-care providers should assess cognitive functioning, which can then allow for determination of appropriate interventions based upon a risk-benefit analysis. In patients with more severe cognitive impairment, more aggressive interventions are indicated.
   A. Both statements are true
   B. The first statement is true; the second statement is false
   C. The first statement is false; the second statement is true
   D. Both statements are false

24. Which of the following is not seen with improved oral health in patients with dementia?
   A. Improved nutritional intake
   B. Worsening sleep patterns
   C. Decreased agitation associated with discomfort/pain
   D. Improved appearance

25. There are seven stages of dementia. The most severe stage is categorized by:
   A. Essentially no ability to speak or communicate and assistance required with most activities (e.g., using the toilet, eating)
   B. Increased forgetfulness, difficulty concentrating, and decreased work performance; individuals get lost more frequently or have difficulty finding the right words
   C. Memory loss may include major relevant aspects of current lives
   D. Personality/emotional changes, such as delusions (believing something to be true that is not), compulsions (repeating a simple behavior, such as cleaning), or anxiety and agitation

26. Niessen et al. developed an index for dental management of patients with dementia. This index evaluates all of the following except:
   A. Ability of the patient/caregiver to brush teeth or clean dentures
   B. Ability of the patient to verbalize their chief complaint
   C. Care-resistant behavior, including assaultive behavior
   D. Ability of the patient to remember a series of unrelated words

27. The Niessen et al. dental index stratifies patients into the following categories:
   i. No dementia disease
   ii. Mild dementia disease
   iii. Moderate dementia disease
   iv. Severe dementia disease
   A. i, ii, iii
   B. i, ii, iii, iv
   C. ii, iii, iv
   D. i and iii

28. In patients with mild dementia disease, which of the following specific treatment considerations is recommended?
   A. Aggressive prevention; use of topical fluorides, daily oral hygiene, oral education of patient and caregivers
   B. Design treatment plan anticipating decline
   C. Restore to function as quickly as possible
   D. All of the above

29. In patients with moderate dementia disease, which of the following general treatment considerations is not recommended?
   A. Sedation may be necessary.
   B. Consider patient and caregiver aesthetic needs.
   C. Consider esthetics when making treatment decisions.
   D. Provide more frequent maintenance/recall visits.

30. In patients with mild dementia disease, which of the following specific treatment considerations is recommended?
   A. Deliver emergency care.
   B. Reduce recommendations for oral hygiene based upon what the patient can perform.
   C. Consider esthetics when making treatment decisions.
   D. Restore patient with fixed rather than removable prostheses.
Don’t forget to floss and floss so you don’t forget? Emerging evidence linking periodontal disease and dementias

COURSE CAN ALSO BE COMPLETED ONLINE AT A LOWER COST. Scan the QR code or go to dentalacademyofce.com to take advantage of the lower rate.

Educational Objectives
1. Understand the current scientific literature about the prevalence, etiology, and stages of dementia
2. Recognize and discuss with patients the association of periodontal diseases and oral bacteria with dementia and Alzheimer’s disease
3. Develop and implement strategies for communication and delivery of oral hygiene and dental care to patients suffering with dementia
4. Evaluate patients’ risk factors and oral hygiene to develop effective intervention and treatment modalities to reduce caries and periodontal disease rates

Course Evaluation
1. Were the individual course objectives met?
   - Objective #1: Yes No
   - Objective #2: Yes No
   - Objective #3: Yes No
   - Objective #4: Yes No

2. To what extent were the course objectives accomplished overall?
   - 5 4 3 2 1 0

3. Please rate your personal mastery of the course objectives.
   - 5 4 3 2 1 0

4. How would you rate the objectives and educational methods?
   - 5 4 3 2 1 0

5. How do you rate the author’s grasp of the topic?
   - 5 4 3 2 1 0

6. Please rate the author’s effectiveness.
   - 5 4 3 2 1 0

7. Was the overall administration of the course effective?
   - 5 4 3 2 1 0

8. Was the usefulness and clinical applicability of this course.
   - 5 4 3 2 1 0

9. Please rate the usefulness of the references.
   - 5 4 3 2 1 0

10. Do you feel that the references were adequate?
    - Yes No

11. Would you take a similar course on a different topic?
    - Yes No

12. If any of the continuing education questions were unclear or ambiguous, please list them.

13. Was there any subject matter you found confusing? Please describe.

14. How long did it take you to complete this course?

15. What additional dental continuing education topics would you like to see?

CANCELLATION AND REFUND POLICY
Participants who are not 100% satisfied can request a refund by contacting Endeavor Business Media. Charges on your statement will show up as Endeavor.
